

The inefficient leadership's role affects the climate change, but the deforestation cannot be neglected.

The deforestation leads to climate change in Pakistan. The biggest threat of climate change is facing by Pakistan due to cutting of trees, which makes it vulnerable. Pakistan only contributes one percent of green house gas emissions. Apart from this, Pakistan has been facing many floods, disasters and heavy rainfall due to climate change. In fact, such consequences are faced by Pakistan because of deforestation. Notably, Pakistan contains less than five percent of its total area under forests. The rate of forest degradation is 1.5 percent which is high alarming. Such activities of cutting the trees increases the risk of climate change in Pakistan. (Asif Saeed, Forest degradation in Pakistan, 2023). In short, deforestation in Pakistan heightens its climate change risk.
