

Global Warming:

There are several man made and natural causes of global warming. The burning of fossil fuels such as coal, oil and natural gas releases enormous amount of greenhouse gases, e.g., Carbon dioxide, methane, nitrogen oxide etc.

The expansion of industries releases pollutants and greenhouse gases that contributes to global warming such as, metal processing industries. volcanic eruption emits a large amount of sulphur dioxide and carbon dioxide that results in global warming for instance Laki eruption that released 120 million tons of sulphur dioxide. Disruption in oceanic circulation patterns, e.g., El Nino leads to global warming. In conclusion, various man induced and natural factors results in global warming that include greenhouse gases, industrialization, volcanic activity and ocean currents.
