

Agricultural development is prerequisite for progress and prosperity of Pakistan, and agricultural development is not possible without irrigation. The water level in Pakistan's rivers fluctuates as per season as water comes to these rivers through rain and from melting of mountain glaciers. In summer water flows are very high leading to teeming of the rivers to the brim. A large quantity of water is lost due to lack of adequate water reservoirs resources. This also results in flooding of settlements adjacent to the rivers causing high destruction of the population. As the winter approaches, the water level in river decreases and in this way water volume for meeting irrigation and other needs also dwindles.

Need of Irrigation system

Proper irrigation system is essential for the progress of Pakistan's agriculture sector. The water level in the rivers, changes continuously. In summer, it rises and results in destruction due to lack of reservoirs. In winter, it decreases and doesn't fulfill the water demand of agriculture.
