

Uncontrollable population growth is being considered a primary cause of global warming. This is because the people's needs to survive are also increased. Thereby, to fulfill their needs, people have compromised environmental sustainability. For instance, people have started to drive more vehicles, migrate to cities, and work in factories.

Moreover, these human activities lead to greenhouse gas emissions, which drive global warming significantly. According to the International Energy Agency (IEA), in 2020, the global population reached 7.6 billion, resulting in a 2.1 percent increase in carbon dioxide emissions compared to 2019. Such data clearly show that population growth is directly proportional to global warming. In a nutshell, this rampant population growth is an unavoidable factor in global warming.
